As you can see the by the graphs above, the waves with overlapping frequency components are considered orthoganol. Wavelets with different oscillation rates are orthoganol. By the magnitude plot at the zero frequency component we can get the DC component. For Psi 01, 10, 11, 21 they are 0, 20, 0 and 0 respectively.

**Report Item 2** The father wavelet is called a corking function because it fills up the holes of the lower frequency components that the mother wavelets do not detect. The wavelet coefficients are different than fourier coefficients because in wavelet analysis, a short modulated window is used to complete the spectral representation for that chunk. After that, the window is shifted along the signal. It is a time-frequency analysis instead a purely frequency analysis.
